## COM6509/4509 — Tutorial Sheet 1 Bayesian and Maximum Likelihood Manipulation of Gaussian Models

## Neil Lawrence

## October 5th, 2012

1. Univariate Gaussian model. A Gaussian density governs a vector of univariate observations,  $\mathbf{t} = \{t_i\}_{i=1}^N$ . The associated error function has the following form.

$$E(\mu) = \sum_{i=1}^{N} (t_i - \mu)^2$$

- (a) Introduce the variance parameter,  $\sigma^2$  and convert the error function to the Gaussian density. Find the maximum likelihood solutions for both  $\mu$  and  $\sigma^2$ .
- (b) Place the following Gaussian prior over the mean,

$$p(\mu) = \frac{1}{\sqrt{2\pi\alpha}} \exp\left(-\frac{1}{2\alpha}\mu^2\right)$$

and compute the marginal likelihood for  $\mathbf{t}$  and the posterior density for  $\mu$ .

2. Maximum likelihood in a multivariate Gaussian. A data set consists of p dimensional vectors,  $\mathbf{t}_{i,:}$  from a matrix  $\mathbf{T} = {\mathbf{t}_{i,:}}_{i=1}^{N}$  (i.e.  $\mathbf{T} \in \Re^{N \times p}$ ). The likelihood is given by

$$p(\mathbf{T}) = \prod_{i=1}^{N} p(\mathbf{t}_{i,:})$$

where the likelihood of each data point is

$$p(\mathbf{t}_{i,:}) = \frac{1}{(2\pi)^{\frac{p}{2}} |\mathbf{C}|^{\frac{1}{2}}} \exp\left(-\frac{1}{2}(\mathbf{t}_{i,:} - \boldsymbol{\mu})^{\top} \mathbf{C}^{-1}(\mathbf{t}_{i,:} - \boldsymbol{\mu})\right).$$

(a) Write down the log likelihood and use the following matrix and vector derivatives

$$\frac{\mathrm{d}\mathbf{x}^{\top}\mathbf{A}\mathbf{x}}{\mathrm{d}\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{A}^{\top}\mathbf{x}$$
$$\frac{\mathrm{d}\log|\mathbf{C}|}{\mathrm{d}\mathbf{C}} = \mathbf{C}^{-1}$$
$$\frac{\mathrm{d}\mathbf{a}^{\top}\mathbf{C}^{-1}\mathbf{a}}{\mathrm{d}\mathbf{C}} = -\mathbf{C}^{-1}\mathbf{a}\mathbf{a}^{\top}\mathbf{C}^{-1}$$

to show that the maximum likelihood solutions for the mean,  $\hat{\mu}$  and covariance matrix,  $\hat{C}$ , are

$$\hat{\boldsymbol{\mu}} = \frac{1}{N} \sum_{i=1}^{N} \mathbf{t}_{i,:},$$
$$\hat{\mathbf{C}} = \frac{1}{N} \sum_{i=1}^{N} (\mathbf{t}_{i,:} - \hat{\boldsymbol{\mu}}) (\mathbf{t}_{i,:} - \hat{\boldsymbol{\mu}})^{\top}.$$

(b) Now consider an independent Gaussian prior over the elements of the mean vector,

$$p(\boldsymbol{\mu}) = \prod_{i=1}^{p} \frac{1}{\sqrt{2\pi\alpha}} \exp\left(-\frac{1}{2\alpha}\mu_{i}^{2}\right)$$

i. Show that this can be written in vector form as follows:

$$p(\boldsymbol{\mu}) = \frac{1}{(2\pi\alpha)^{\frac{p}{2}}} \exp\left(-\frac{1}{2\alpha}\boldsymbol{\mu}^{\top}\boldsymbol{\mu}\right)$$

- ii. Now compute the posterior density for  $\boldsymbol{\mu}$ ,  $p(\boldsymbol{\mu}|\mathbf{T})$ . Write down the terms that remain that would be required for the marginal likelihood of  $\mathbf{T}$ ,  $p(\mathbf{T})$  (note given the matrix algebra we've covered you won't be able to write down the full form of the marginal likelihood).
- 3. **Regression with a basis function model**. Assume that we wish to perform a nonlinear regression by computing a set of basis functions, for example,

$$\phi_j(\mathbf{x}_{i,:}) = \exp\left(-\frac{1}{2\ell_j^2}(x_i - \mu_j)^2\right),$$

where  $\mu$  is a location parameter and  $\ell$  is a width parameter for the *j*th basis function. For each data point we take the *m* basis functions and write them in a vector of the following form

$$\boldsymbol{\phi}_{i,:} = [\phi_1(\mathbf{x}_{i,:}) \dots \phi_m(\mathbf{x}_{i,:})]^\top$$

and the complete set of basis functions is written in a matrix,  $\mathbf{\Phi} \in \Re^{N \times m}$  of the following form,

$$oldsymbol{\Phi} = egin{bmatrix} oldsymbol{\phi}_{1,:} oldsymbol{\phi}_{2,:} \dots oldsymbol{\phi}_{N,:} \end{bmatrix}^ op$$
 .

If we assume Gaussian noise we can write down the Gaussian likelihood of a single data point, i,

$$p(t_i|\boldsymbol{\phi}_{i,:}, \mathbf{w}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{1}{2\sigma^2}(t_i - \mathbf{w}^\top \boldsymbol{\phi}_{i,:})^2\right).$$

(a) Assume the noise is independent and identically distributed and write down the corresponding likelihood and log likelihood of the entire data set.

(b) Show that the maximum likelihood solution for  $\mathbf{w}$  is given by

$$\hat{\mathbf{w}} = \left( \mathbf{\Phi}^{\top} \mathbf{\Phi} 
ight)^{-1} \mathbf{\Phi}^{\top} \mathbf{t}.$$

(c) Consider a Gaussian prior over the parameters, w,

$$p(\mathbf{w}) = \prod_{i=1}^{m} \frac{1}{\sqrt{2\pi\alpha}} \exp\left(-\frac{1}{2\alpha}w_i^2\right).$$

Show that the posterior for  ${\bf w}$  is given by a Gaussian with covariance

$$\mathbf{C}_w = \left(\frac{1}{\sigma^2} \mathbf{\Phi}^\top \mathbf{\Phi} + \alpha^{-1} \mathbf{I}\right)^{-1}$$

and mean

$$\boldsymbol{\mu}_w = rac{1}{\sigma^2} \mathbf{C}_w \mathbf{\Phi}^\top \mathbf{t}$$

- i. Compare the solution for the maximum likelihood and the posterior mean over  $\mathbf{w}$ . When do they become the same?
- ii. What problems occur for the maximum likelihood solution if m > N?
- (d) Show that the marginal likelihood of the data set is given by

$$p(\mathbf{t}|\mathbf{X}, \alpha, \sigma^2) = \frac{1}{(2\pi)^{\frac{N}{2}} |\mathbf{K}|^{\frac{1}{2}}} \exp\left(-\frac{1}{2} \mathbf{t}^\top \mathbf{K}^{-1} \mathbf{t}\right)$$

where

$$\mathbf{K} = \alpha \mathbf{\Phi} \mathbf{\Phi}^\top + \sigma^2 \mathbf{I}$$

by using the matrix inversion formula:

$$(\mathbf{A} + \mathbf{B}\mathbf{C}\mathbf{D})^{-1} = \mathbf{A}^{-1} - \mathbf{A}^{-1}\mathbf{B}(\mathbf{C}^{-1} + \mathbf{D}\mathbf{A}^{-1}\mathbf{B})^{-1}\mathbf{D}\mathbf{A}^{-1}.$$

Tutorial Sheet 1 Answers  $E(\mu) = \sum_{i=1}^{2} (t_i - \mu)^2$ 1 A)  $P(\underline{t}|\mu, \sigma) = \frac{1}{(2\bar{u}\sigma^2)^{N/2}} \exp\left(-\frac{N}{(t_i - \mu)^2}\right)$   $\frac{1}{(2\bar{u}\sigma^2)^{N/2}} \exp\left(-\frac{N}{(t_i - \mu)^2}\right)$ Loy likelihood  $\frac{\log P(t|\mu,\sigma^2) \simeq -N \log \sigma^2 - N \log 2\pi - \frac{N}{2} \log (t_c - \mu)^2}{2 - \frac{N}{2} \log 2\pi - \frac{N}{2} \log 2\pi$  $d \log P(t|_{\mu,s^2}) = -N + 2 (t;-\mu)^2$ 2.82 121 - 7×4 Set to zero to Find Fixed point equation  $\frac{N}{2\delta^{2}} = \frac{2}{c^{2}} \frac{(t_{i}^{2} - m)^{2}}{2\delta^{2}}$ Multiply both sider by 204  $\frac{N}{V^2} = \frac{1}{2} \frac{\left(t_i - \mu\right)^2}{\left(t_i - \mu\right)^2}$
